

LibrettOS: A Dynamically Adaptable Multiserver-Library OS

Ruslan Nikolaev, Mincheol Sung, Binoy Ravindran

16th ACM SIGPLAN/SIGOPS International Conference on
Virtual Execution Environments (VEE 2020), March 17, 2020

Motivation

- ▶ The monolithic OS design is inadequate for modern systems
 - ▶ Lack of isolation, failure recovery, large trusted computing base (TCB)
 - ▶ Kernel-bypass libraries or library OS improve performance

[Herder et al. ACSAC'06],
[Nikolaev et al. SOSP'13],
[Kantee login'14],
[Lankes et al. ROSS'16],
[Decky 2017]

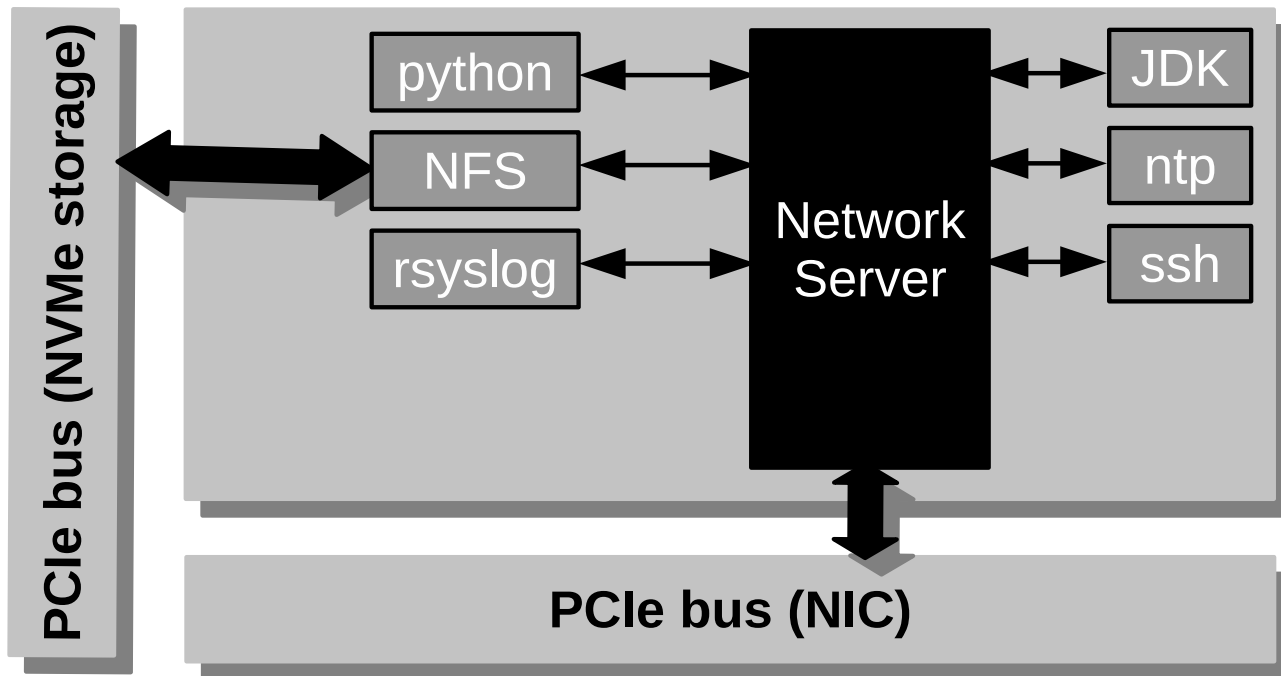

Motivation

- ▶ The monolithic OS design is inadequate for modern systems
 - ▶ Lack of isolation, failure recovery, large trusted computing base (TCB)
 - ▶ Kernel-bypass libraries or library OS improve performance
- ▶ Multiple OS paradigms *seamlessly* integrated in the *same* OS are desirable
 - ▶ Application-specific requirements (performance, security)
 - ▶ Shared driver code base
 - ▶ No code rewrite (POSIX compatibility)
 - ▶ Limited physical (e.g., SR-IOV) resources
 - ▶ Dynamic switch

[Herder et al. ACSAC'06],
[Nikolaev et al. SOSP'13],
[Kantee login'14],
[Lankes et al. ROSS'16],

Example: Server Ecosystem

- ▶ The network server for most applications

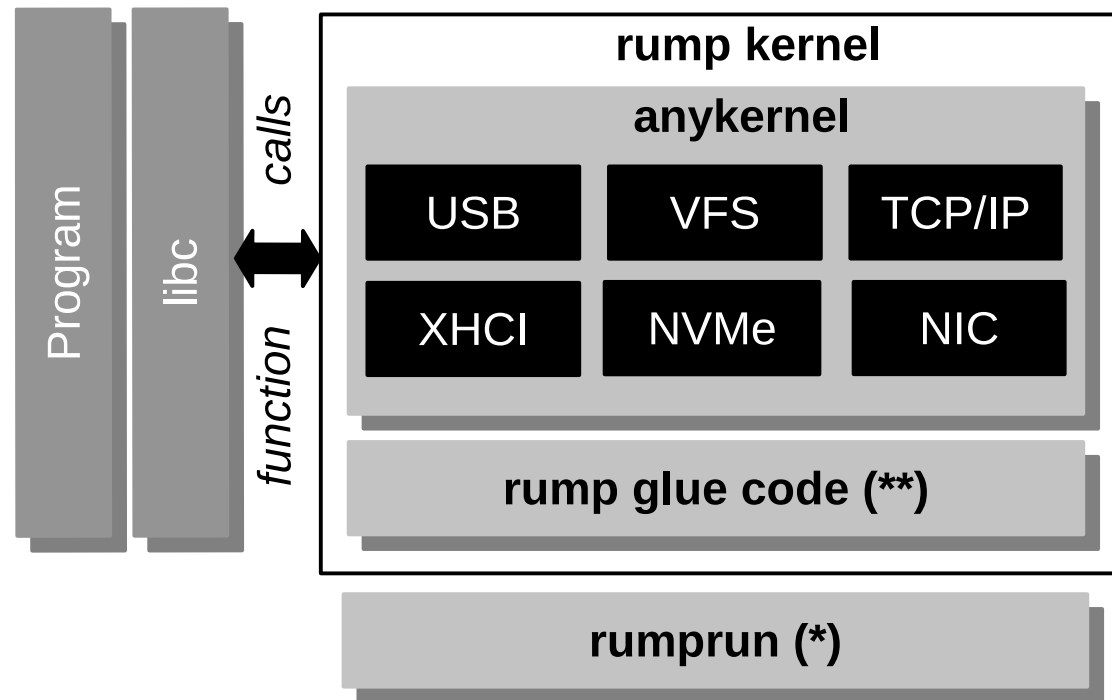

Example: Server Ecosystem

- ▶ Direct access for certain applications

Rump Kernels and Rumprun

- ▶ The concept is introduced by Antti Kantee and NetBSD community
- ▶ NetBSD code consists of *anykernel* components which can be used in both kernel and user space
- ▶ The *rumprun* unikernel is effectively a library OS

Rump Kernels and Rumprun

▶ Pros

- ▶ Very flexible
- ▶ Reuse most of NetBSD code (both drivers and the user-space environment)
- ▶ The rump kernel part is upstreamed
- ▶ A permissive license (2-Clause BSD) for the most code

▶ Cons

- ▶ Rumprun lacks SMP and Xen HVM support
- ▶ The unikernel model is not always suitable

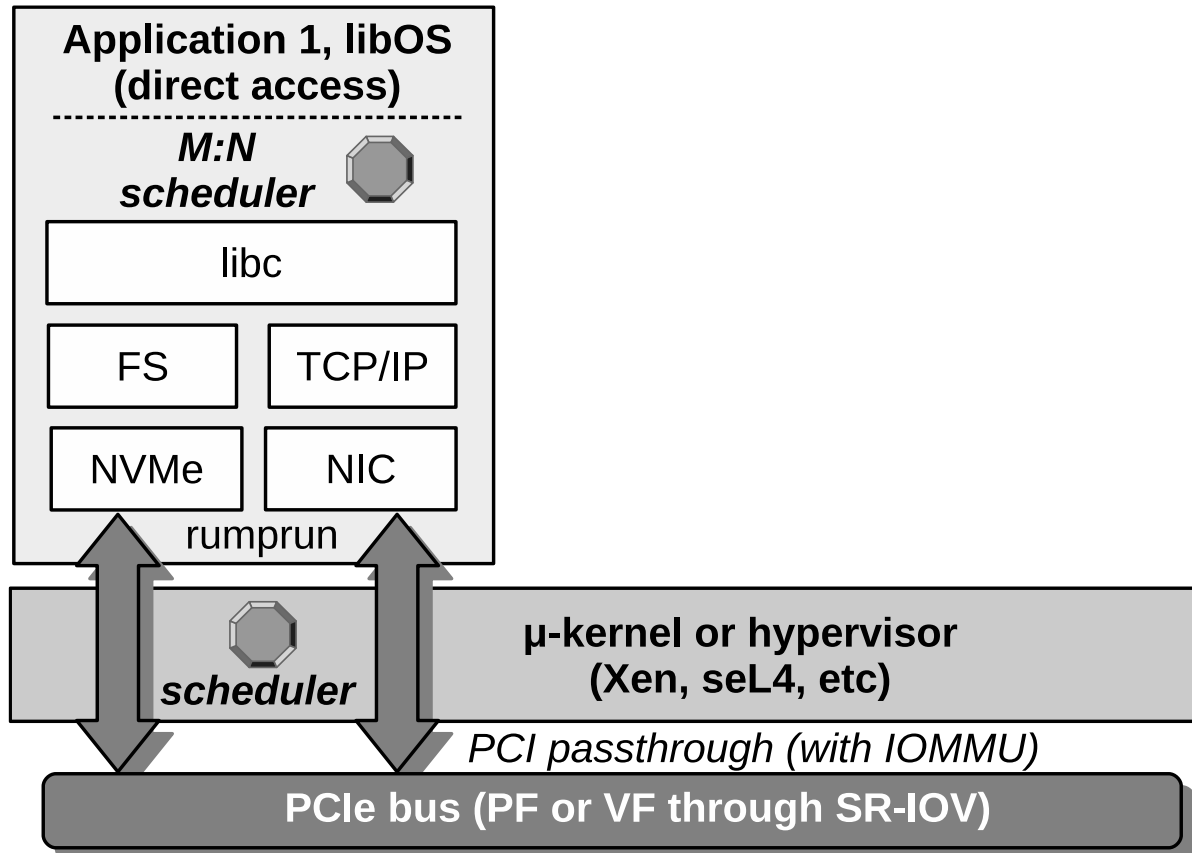

LibrettOS

- ▶ Based on rumprun
 - ▶ Adds SMP and Xen HVM support
- ▶ Reuses NetBSD's device drivers and user-space environment
- ▶ Uses the Xen hypervisor
- ▶ A more advanced OS model
 - ▶ Our prototype implements the *network server*
 - ▶ Applications can also directly access resources (NIC, NVMe)
 - ▶ Dynamic switch

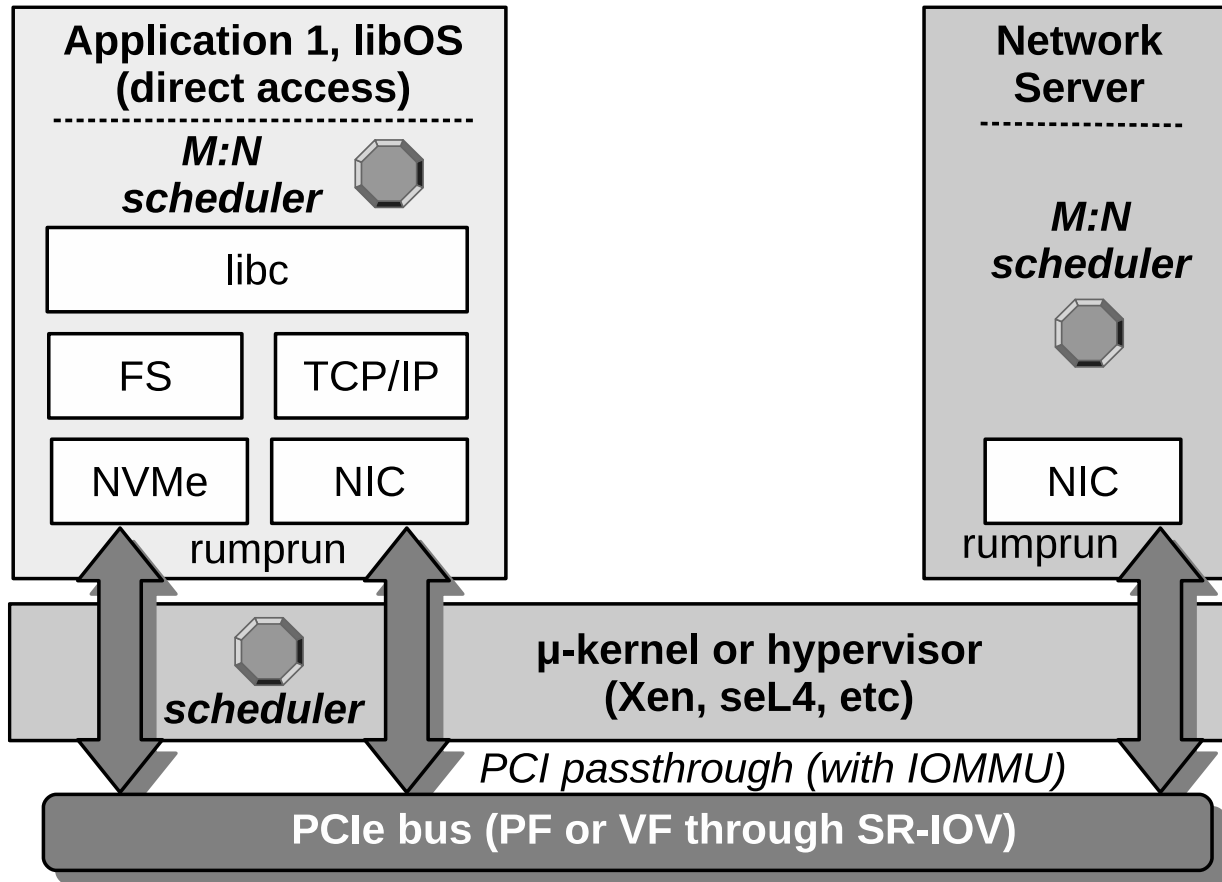

LibrettOS Architecture

- ▶ Direct mode applications

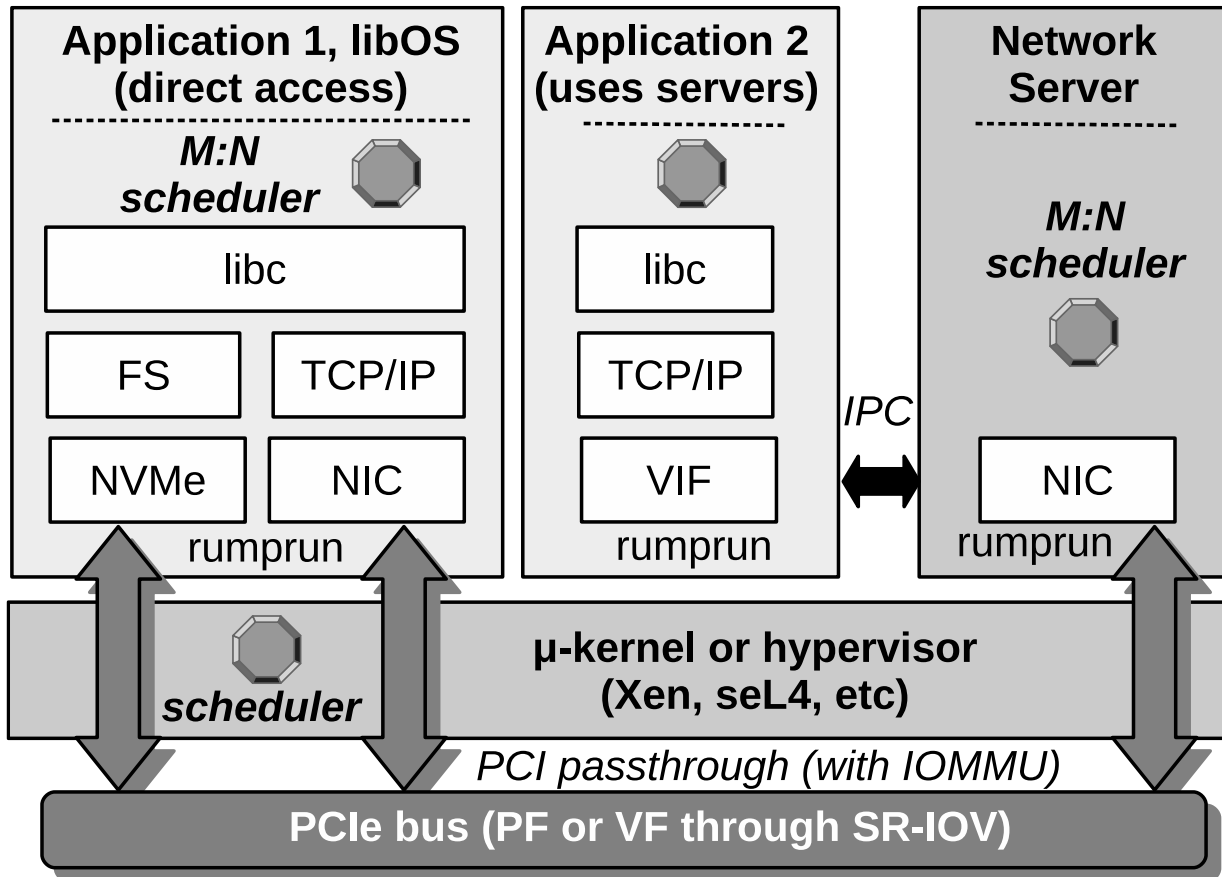

LibrettOS Architecture

- ▶ Network server

LibrettOS Architecture

- ▶ Applications that use servers

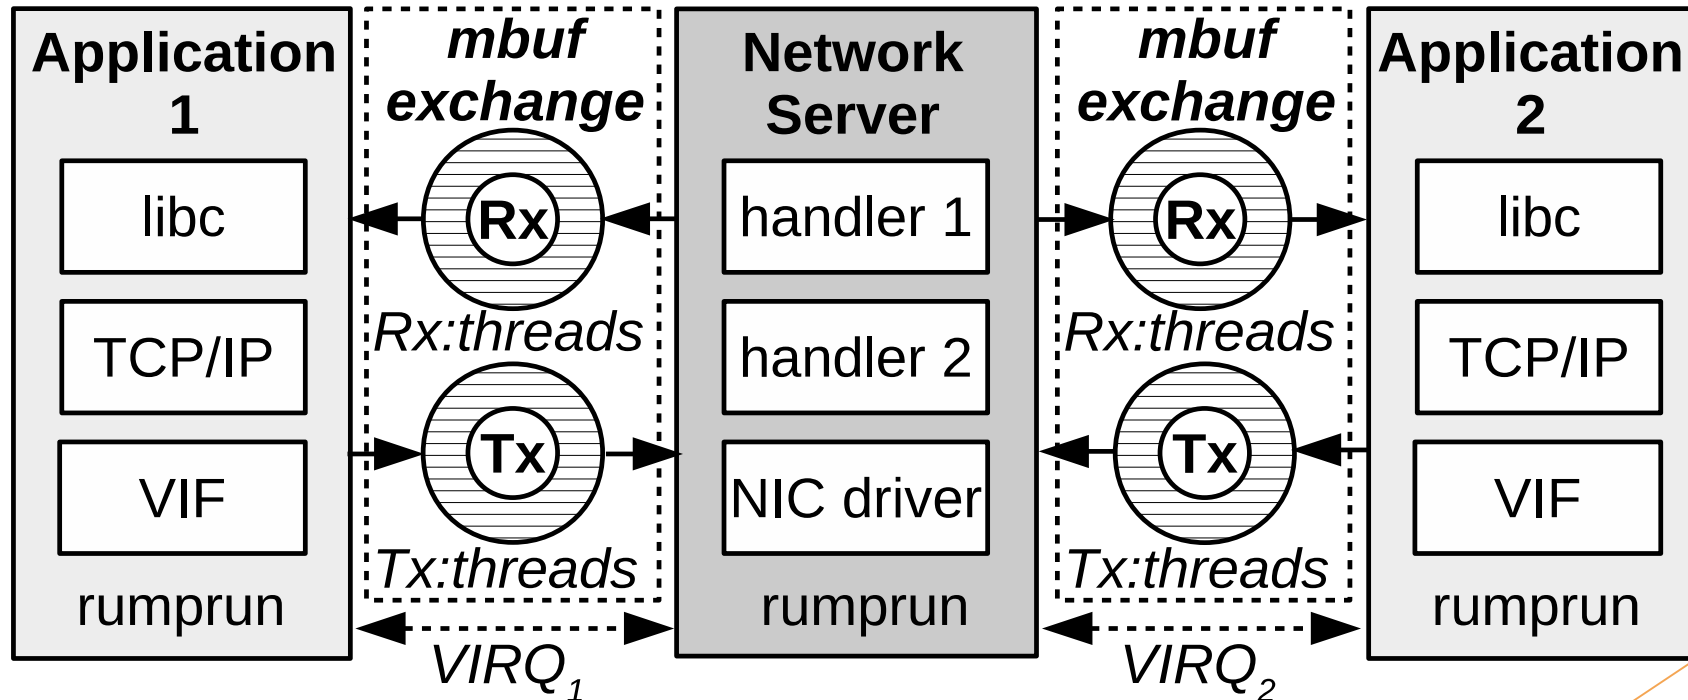

Network Server

- ▶ A low-level design (direct L2 forwarding)
 - ▶ TCP runs in the application address space
 - ▶ A full recovery is possible as long as TCP does not time out
 - ▶ Accommodates two paradigms easily
 - ▶ A dynamic switch is feasible
- ▶ Fast IPC
 - ▶ Uses Xen-specific capabilities (e.g., shared memory, VIRQ)
 - ▶ Lock-free queues

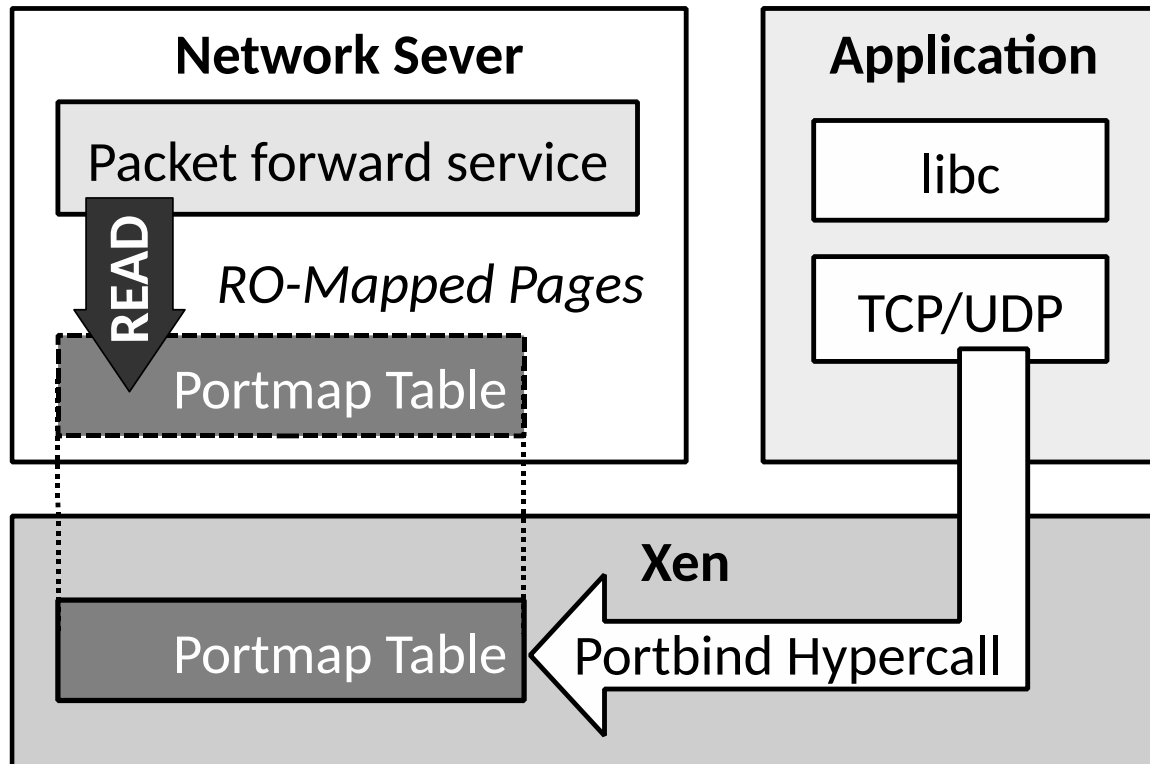

Network Server

- ▶ The IPC channel exchanges mbufs
 - ▶ Rx/Tx lock-free ring buffers (shared memory)
 - ▶ Virtual interrupts (VIRQ)

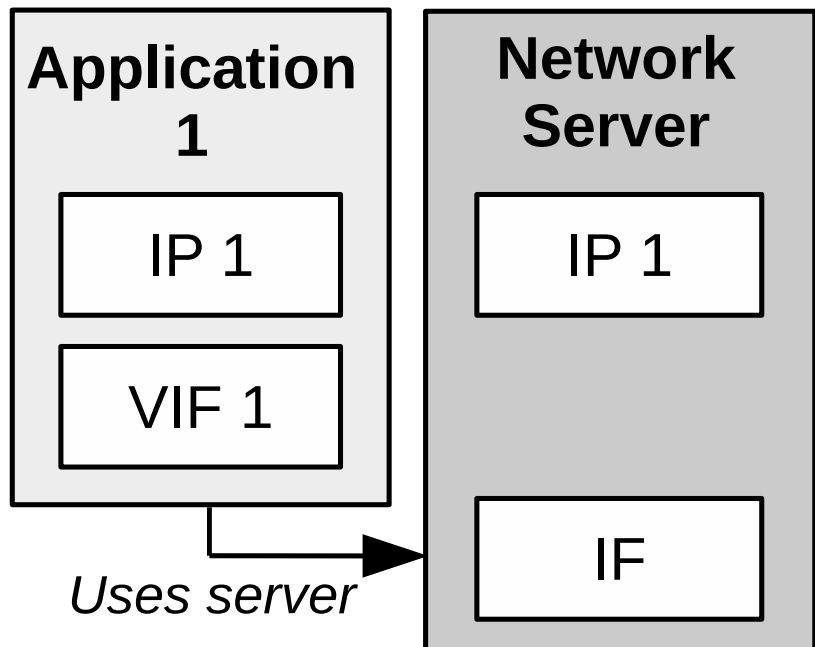

Network Server: Portmap Table

- ▶ The portmap (port-to-domain map) table is kept in Xen
 - ▶ 64K entries for TCP and 64K entries for UDP
 - ▶ Can be accessed (read-only) by the network server
 - ▶ Applications issue a port-bind hypercall

Dynamic switch

- ▶ Applications that do not need a dynamic switch, use the network server and share the same IP

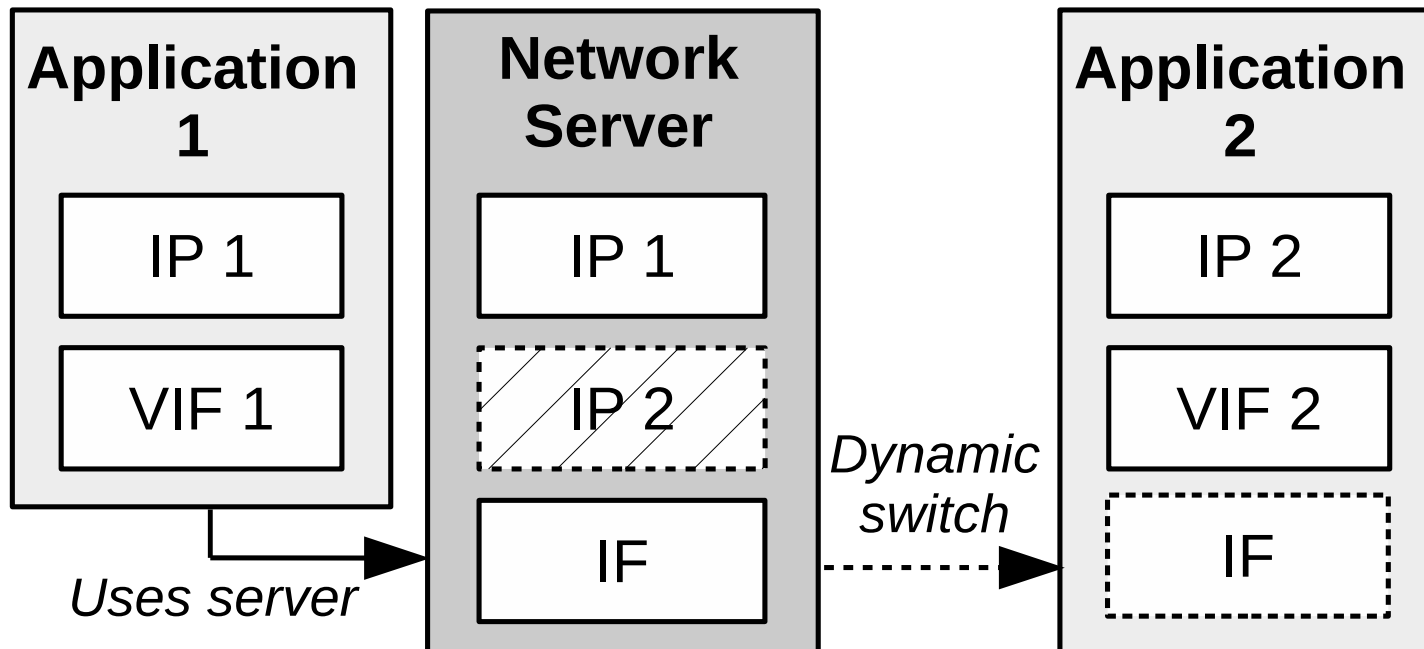

Dynamic switch

- ▶ Applications that need a dynamic switch, reserve a dedicated IP when connecting to the network server.
 - ▶ Initially their VIF redirects packets the network server

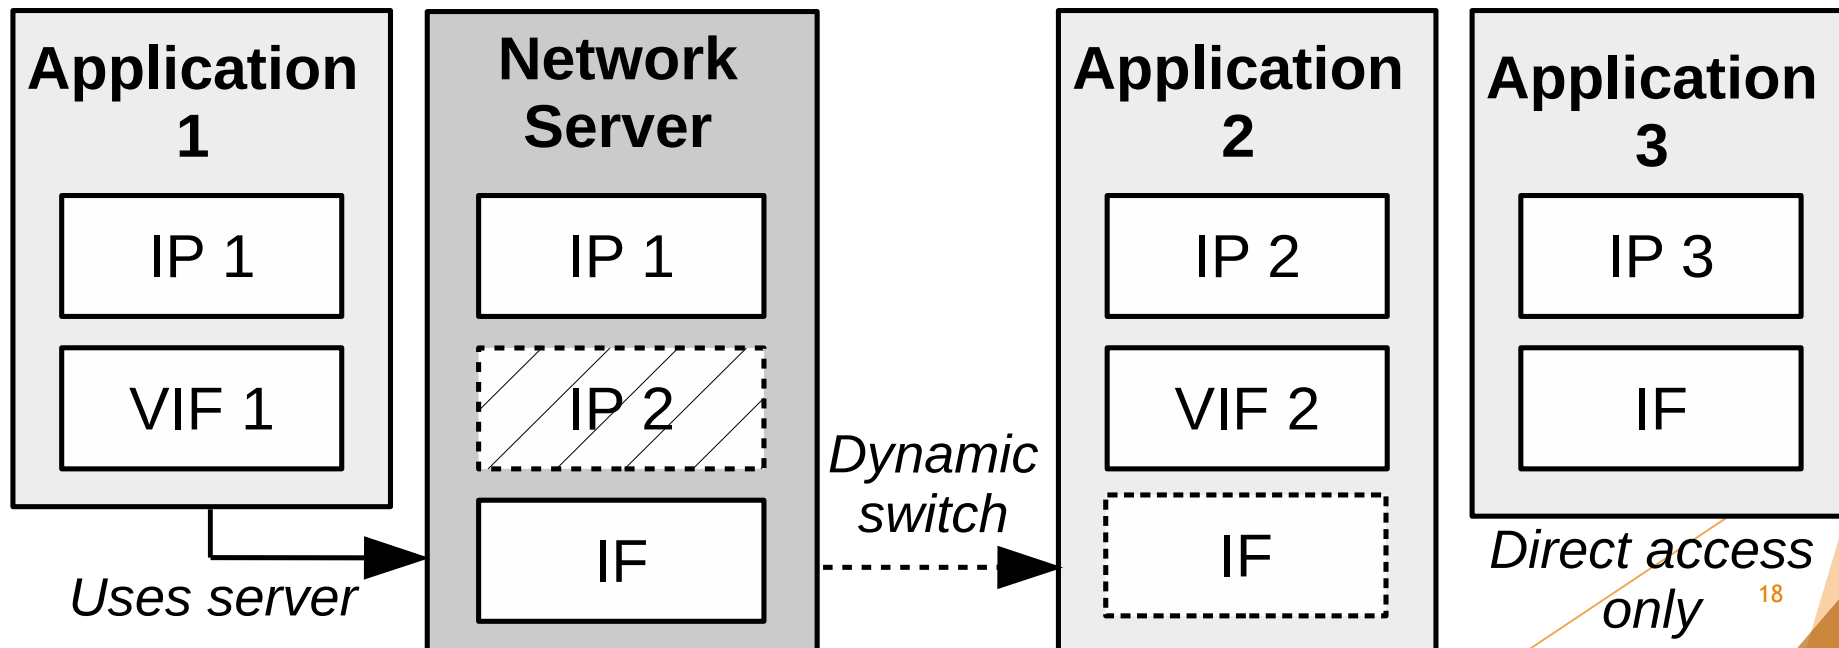

Dynamic switch

- ▶ When the dynamic switch is requested, the corresponding IP is deactivated on the network server side, and the corresponding physical interface is configured

Dynamic switch

- ▶ Applications that always need direct access avoid an intermediate VIF and access the physical interface directly

Evaluation: System Configuration

Processor	2 x Intel Xeon Silver 4114, 2.20GHz
Number of cores	10 per processor, per NUMA node
HyperThreading	OFF (2 per core)
TurboBoost	OFF
L1/L2 cache	64 KB / 1024 KB per core
L3 cache	14080 KB
Main Memory	96 GB
Network	Intel x520-2 10GbE (82599ES)
Storage	Intel DC P3700 NVMe 400 GB

Xen 4.10.1
Linux 4.13
NetBSD 8.0 + NET_MPSAFE
Jumbo Frames (mtu = 9000)

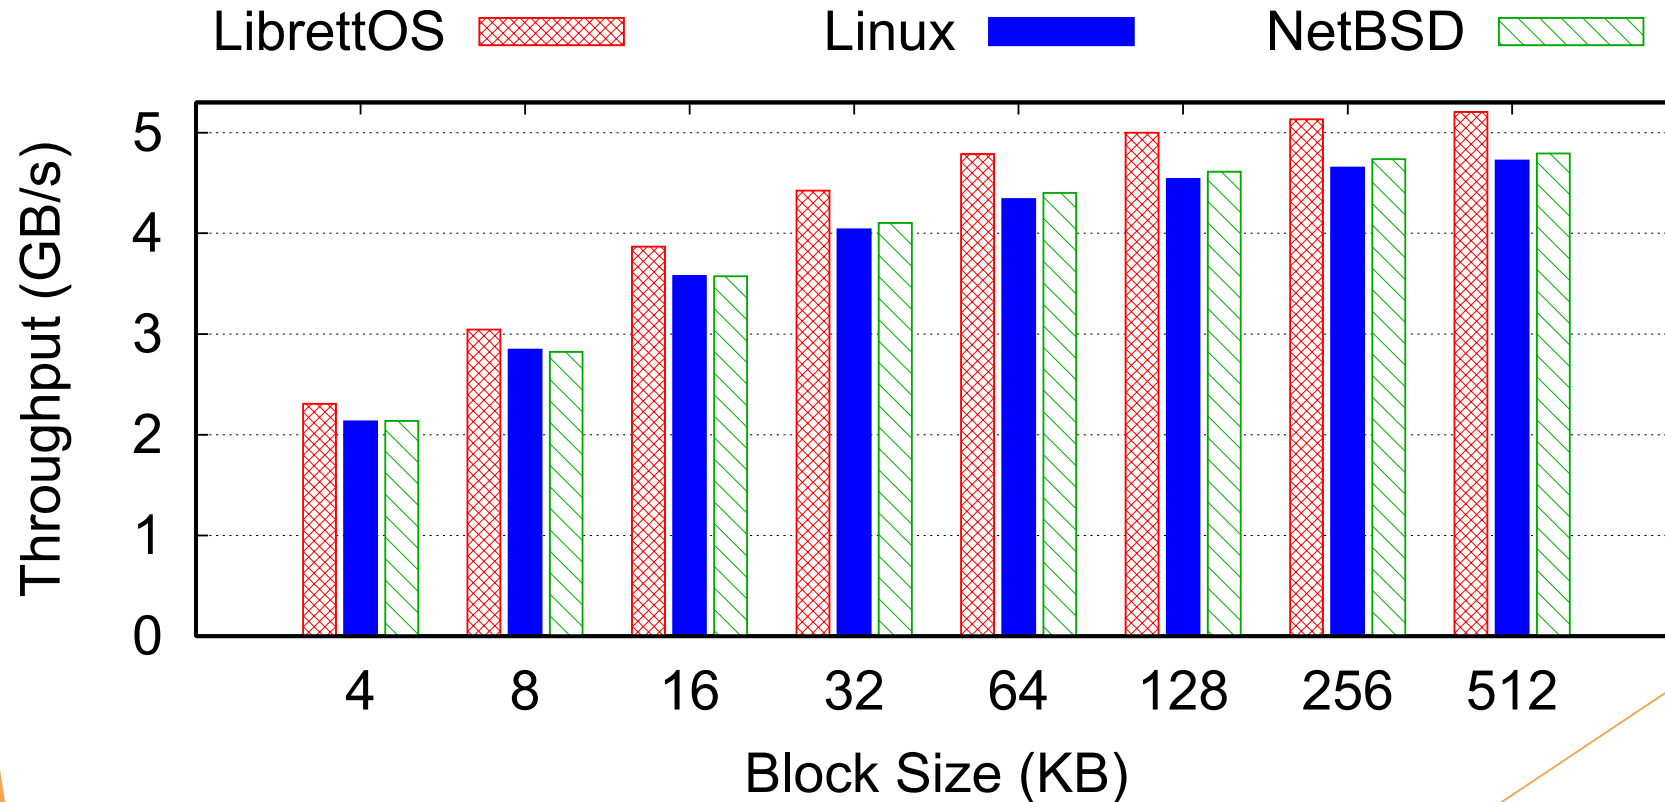

Evaluation

- ▶ NetPIPE: network throughput (a ping pong benchmark)
 - ▶ 64 bytes .. 512 K
 - ▶ All systems except the original Rumprun-PV have comparable performance

Evaluation

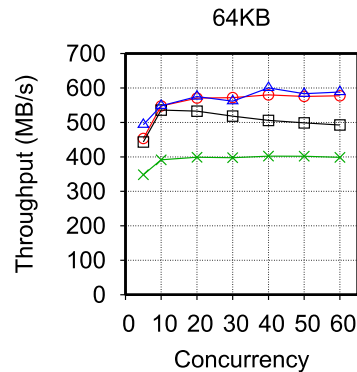

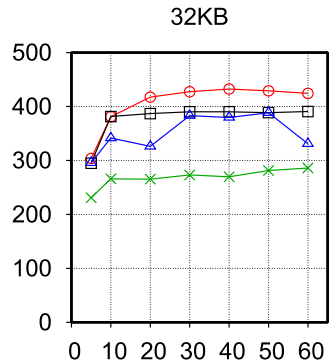

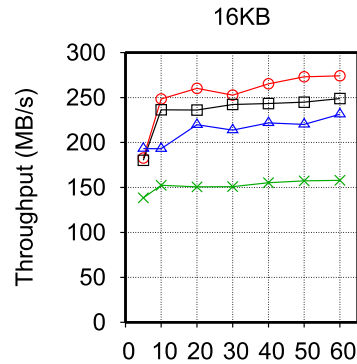

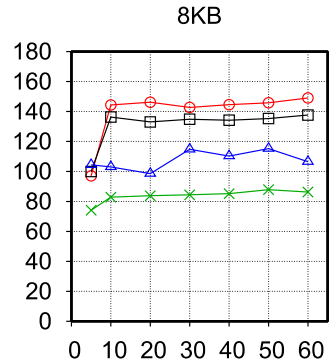

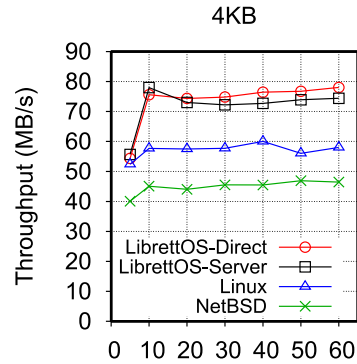

- ▶ NFS server
 - ▶ Executing Sysbench/FileIO from the client machine
 - ▶ Direct NVMe initialized with ext3, mixed I/O

Evaluation

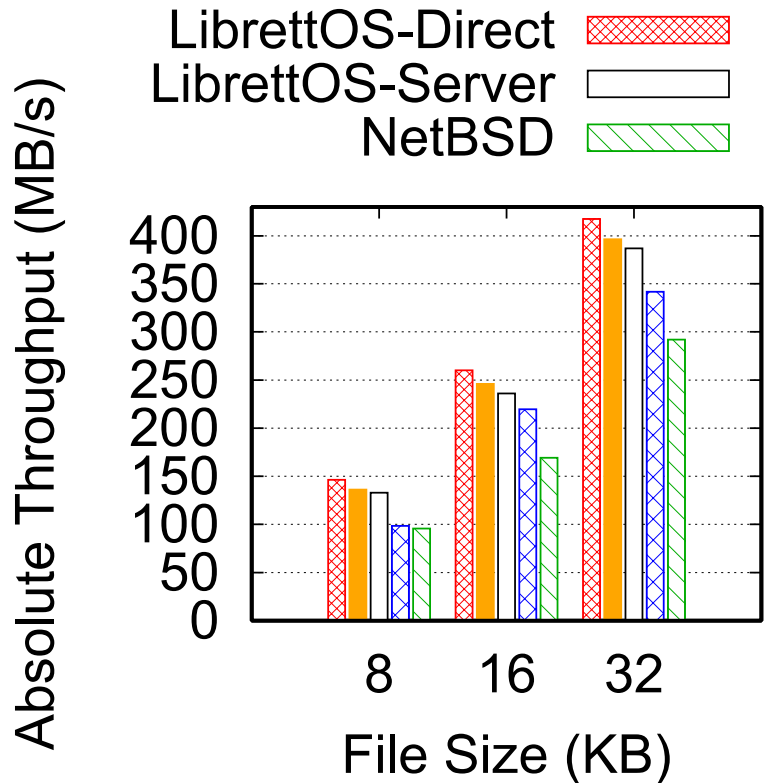

- ▶ Nginx HTTP server
 - ▶ 10,000 requests from the client side
 - ▶ Concurrency 1 .. 60
 - ▶ Blocks 4K .. 128K
 - ▶ LibrettOS has a better performance for smaller blocks

Evaluation

- ▶ Nginx: Dynamic Switch
 - ▶ Concurrency 20
 - ▶ LibrettOS-Hybrid: 50% in direct mode and 50% in server mode

Evaluation

- ▶ Memcached (a distributed memory caching system)
 - ▶ The memcache_binary protocol
 - ▶ 1:10 of SET/GET operations (read-dominated)
 - ▶ Each thread runs 10 clients, each client performs 100,000 operations

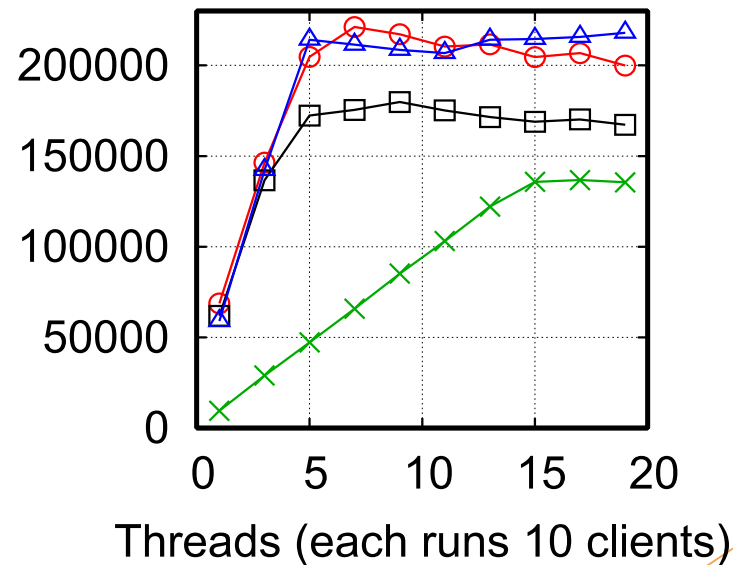

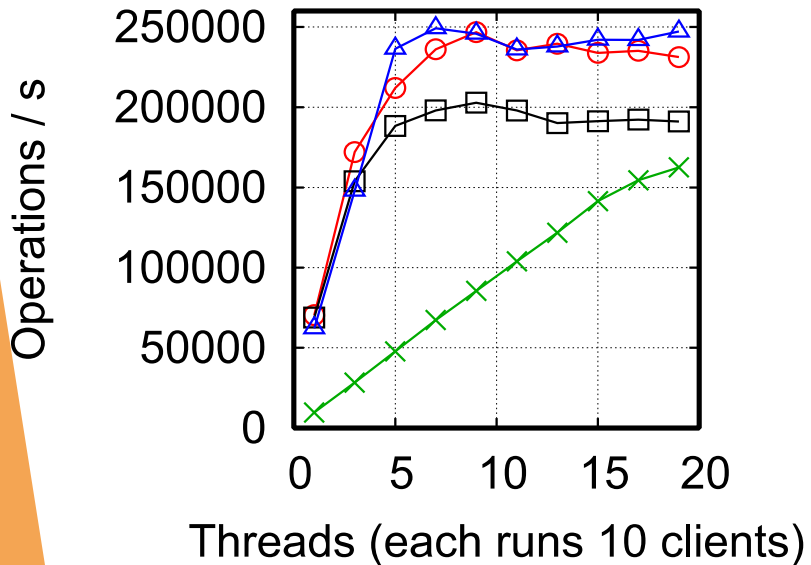

LibrettOS-Direct —○—
LibrettOS-Server —□—

Linux —△—
NetBSD —×—

32 bytes

8KB

Evaluation

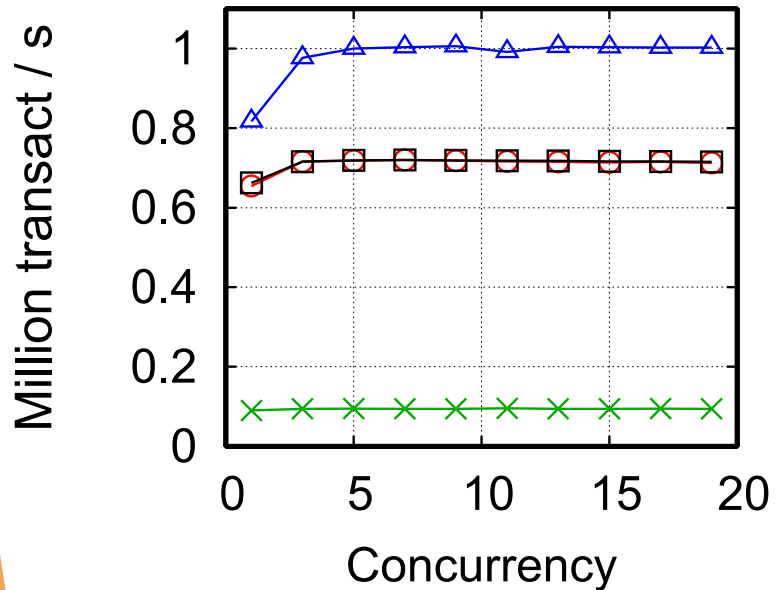

- ▶ Redis (in-memory key-value store)
 - ▶ 1,000,000 SET/GET operations, 128 bytes
 - ▶ Various number of concurrent connections

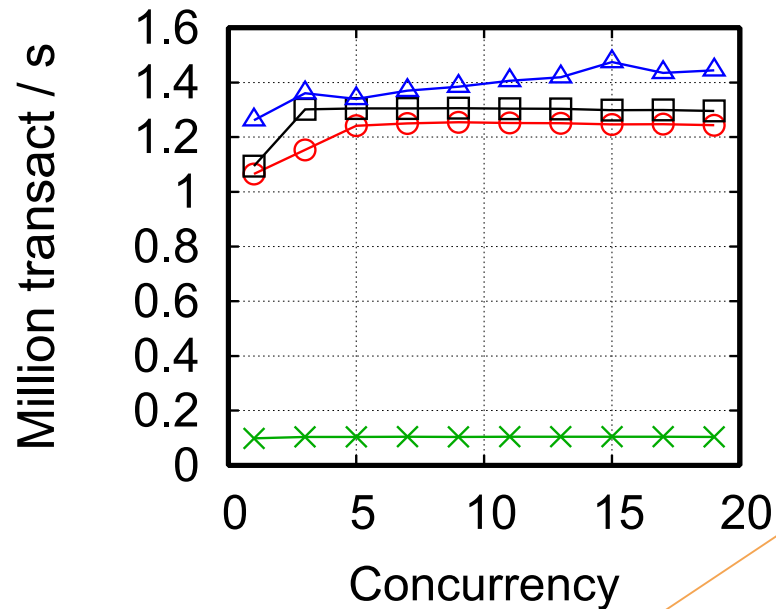

LibrettOS-Direct —
LibrettOS-Server —

Linux —
NetBSD —

128 bytes (Set)

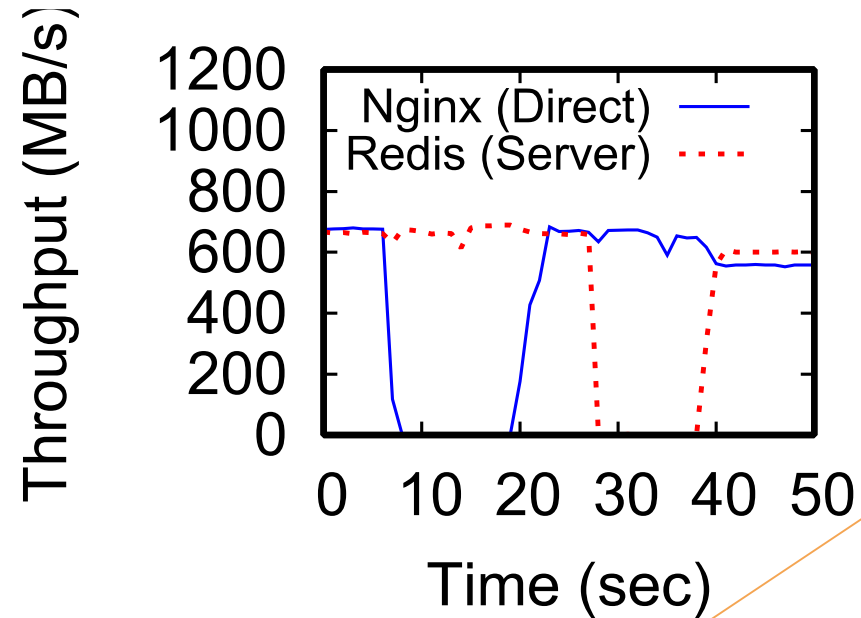

128 bytes (Get)

Evaluation

- ▶ Failure recovery
 - ▶ One application (Nginx uses the network server)
 - ▶ Two applications: Nginx and Redis

Related Work

- ▶ Multiserver OS
 - ▶ MINIX 3 [ACSAC'06], HelenOS, QNX
- ▶ Multiserver approaches for monolithic systems
 - ▶ SawMill, VirtuOS [SOSP'13], Snap [SOSP'19]
- ▶ Kernel-bypass libraries
 - ▶ DPDK, SPDK
- ▶ Library OS approaches
 - ▶ IX [OSDI'14], Arrakis [OSDI'14]
- ▶ Unikernels
 - ▶ UKL [HotOS'19]

Conclusions

- ▶ LibrettOS is an OS that unites two models: multiserver and library OS
- ▶ LibrettOS is the first to seamlessly integrate these two models
 - ▶ The same driver base (inherited from NetBSD)
 - ▶ Applications do not need to be modified
- ▶ A dynamic switch is possible
 - ▶ Applications can switch from the network server to direct mode with no interruption at runtime
- ▶ Our prototype solves a number of technical challenges
 - ▶ SMP support, Xen HVM support
